Preliminary Project

Instructions

When you start design phase of the project the most important is a clear view of the problem your application solves and thus the main user of your application (i.e. "The Story").
In design and implementation phases of the project you can (and should) use Standard Library classes and algorithms. Try to separate the logic of the application from the user interface - this will not only facilitate automatic testing but also will simplify design and implementation.

Preliminary Project documentation should contain four parts:

- Description of the project (“The Story”)

  The description defines functionalities of the classes and relations between them. Some limits and restrictions should be specified there. The functionality of each class should be simple, anyway consistent and complete (considering all consequences of the particular choices). Description is presented in the natural language up to one page.

- Case study (a memory map)

  It should be a drawing presenting relations between number of objects from different classes. These relations should be representative and should show how particular pointers are organized in a coherent way.

- Declaration of the classes

  Written in C++ declaration of the classes should present declarations of all public methods and private data structures of each class. In comments special behaviors of methods should be explained.

- Testing

  Written in C++ scenarios of correct and incorrect cases, with explanations what sequences of instructions should demonstrate.

It would be very convenient to aggregate all parts into one pdf document to give quick access to all elements of the preliminary project.
